Fiscal Year:	FY 2020	**Task Last Updated:**	FY 11/05/2020
PI Name:	Vanapalli, Siva		
Project Title:	Determining Muscle Strength in Space-Flown Caenorhabditis elegans		
Division Name:	Space Biology		
Program/Discipline:			
Program/Discipline--Element/Subdiscipline:	SPACE BIOLOGY--Developmental biology		
Joint Agency Name:		**TechPort:**	No
Human Research Program Elements:	None		
Human Research Program Risks:	None		
Space Biology Element:	(1) Cell & Molecular Biology (2) Animal Biology: Invertebrate		
Space Biology Cross-Element Discipline:	(1) Reproductive Biology (2) Developmental Biology (3) Musculoskeletal Biology		
Space Biology Special Category:	(1) Translational (Countermeasure) Potential		
PI Email:	siva.vanapalli@ttu.edu	**Fax:**	FY
PI Organization Type:	UNIVERSITY	**Phone:**	806-742-1757
Organization Name:	Texas Tech University		
PI Address 1:	Chemical Engineering		
PI Address 2:	6th Street and Canton, Mail stop 3121

Performance Goal No.:			
Performance Goal Text:			

Task Description:	A major impediment to long-duration space travel is loss of muscle mass and strength during spaceflight. Surprisingly, the small worm Caenorhabditis elegans is a good, cost-effective model for studying the effects of spaceflight upon muscle. Our past experiments on Earth and on the International Space Station (ISS) have shown that the expression of key muscle genes that encode members of a muscle attachment complex is reduced in C. elegans during spaceflight. A key open question is if and how these changes in gene expression result in reduced muscle strength in response to spaceflight. While reduced force production is documented for astronauts, it is yet to be demonstrated for C. elegans. To address this critical knowledge gap, we developed a tiny new device that enables continuous measurement of worm muscle forces. Using this device, on Earth, we have shown that defects in muscle attachment complexes lead to decline in worm muscle strength. Motivated by these past flight data and ground results, we propose to (a) demonstrate the flight-readiness of our miniaturized device for quantitative characterization of muscle strength of C. elegans, (b) test our hypothesis, based on past flight data, that muscle strength decreases in flight as a result of altered muscle gene expression in the worm, and (c) quantify muscle strength loss in spaceflight across multiple worm generations. Successful measurements of muscle strength in flight will make C. elegans a much more complete and comprehensive genomic model for muscle physiology, enabling meaningful translation of discoveries made in C. elegans to astronauts. Our proposed studies have important spin out implications for sarcopenia (an urgent public health problem on Earth) and may produce a terrestrial model for testing potential therapeutic interventions for muscle strength decline in flight.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	Our studies have important spin out implications for sarcopenia (an urgent public health problem on Earth) and may produce a terrestrial model for testing potential therapeutic interventions for muscle strength decline in flight.
Task Progress:	Progress report duration: 05/19/2019 – 04//2020 During this project period, the Principal Investigator's (PI's) team made progress in the following areas: (1) Pre-Experiment Verification Test (EVT) progress, (2) EVT trial, (3) Post-EVT science testing. Pre-EVT progress Worm culture: We have optimized the conditions for worm culture in the fluorinated ethylene propylene (FEP) bags with culture volumes of 20 mL. We found that an inoculum concentration of 1000 larvae/mL is sufficient for sub-cultures and for animals to grow within the temperature range of 16C – 20C. These culture conditions allow a maximum launch delay of 7 days. NemaFlex device: We have designed and optimized the NemaFlex chamber design to enable size-based sorting of animals from the unsynchronized cultures present in the FEP bags. We have also developed a protocol for loading worm cultures into this device that now is capable of providing strength data from atleast 30 gravid adults. We have worked with BioServe to build the worm loading apparatus (WLA) that integrates the NemaFlex device. The basic version of the apparatus was tested in the PI's laboratory and recommendations have been provided to BioServe for improvements to be made. The improved WLA was tested in the EVT trial. Multigenerational studies: The PI team has conducted multigenerational studies in their laboratory. Under these culture conditions we measured strength of wild-type and dys-1 animals. Our results show that the strength of wild-type and dys-1 animals do not change over the 7 generations studied. EVT trial at BioServe Multigenerational growth studies were conducted at BioServe with the goal of measuring muscle strength of wild-type and dys-1 animals. Post EVT science testing Testing with new C. elegans Maintenance Medium (CeMM). We started testing with new CeMM to assess culture health and muscle strength. The culture density of the animals was between 1000 – 1350 adults/mL, which meets the ERD success criterion. The muscle strength of animals at timepoints of weeks 1, 3, 5, and 7 also did not show any difference for wildtype animals. Multigenerational studies for dys-1 are pending. [Ed. note October 2020: Compiled from PI progress report submitted to NASA Ames]
