Performance Goal Text:			

Task Description:	NOTE: Continuation of "Team Task Switching in Astronaut Crews on the International Space Station: Integrating Multiteam Membership, Multiteam Systems, Multitasking, & Multidimensional Networks to Monitor & Enable Functional Work Shifts in Astronaut Crews," grant NNX15AK73G, due to Principal Investigator move to Northwestern University from Georgia Tech in Fall 2016. We are at the dawn of a new era of human space exploration. Moving beyond low Earth orbit and the relative safety of the International Space Station (ISS) toward near-Earth asteroids and Mars presents previously unimaginable opportunities as well as organizational challenges. One significant challenge is the complexity of the operating environment within which astronauts will work. This complexity will place enormous demands on astronauts, and research is needed that develops concrete countermeasures to mitigate the risks stemming from performance decrements due to inadequate cooperation, coordination, communication, and psychosocial adaptation within a team. Astronauts will push the bounds of human cognitive and social functioning as they multitask across tasks, teams, and tools working toward personal, team, and system goals. This multidisciplinary research project is designed to help them do just that. This investigation into team task switching leverages: (1) agent-based models to understand how task switching behavior and performance-related switching costs occur based on dynamic interplay between independent and interdependent tasks, (2) laboratory experiments conducted in two multiteam systems laboratories (one at Georgia Tech, the other at Northwestern) to test the theoretical model derived from agent-based models, (3) unobtrusive data collection strategies to capture information on the tasks and complex social network structures of ISS crew members, (4) design of interventions to enable adaptive team task switches using virtual experiments, (5) validation of intervention strategies using one of NASA's space analogs, and (6) development of a dashboard decision aid to anticipate and pre-empt dysfunctional task switching. An innovative feature of our investigation is the use of a multidimensional network approach to characterize and model the switches between tasks, tools, teams, and multi-team systems. The combined outputs of this proposed multi-disciplinary project speak directly to NASA Human Research Program's (HRP's) identified team gaps for autonomous, long duration, and/or long distance exploration missions associated with the need to identify (1) key threats to the team (Team Gap 1), (2) countermeasures to support team function (Team Gap 3), (3) validated methods that can be used to maintain team function (Team Gap 5), and (4) psychological and psychosocial factors, measures, and combinations thereof that can be used to compose highly effective crews (Team Gap 8). [Ed. note Sept 2020: HRP Gaps have changed since original proposal--see Human Research Roadmap https://]
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	Previous models of task switching revolve around task and individual factors that affect work efficiency as individuals move from task to task throughout their workday. However, individuals not only accomplish tasks individually using one technological tool, they do so as members of multiple teams using a variety of technologies. Our research on team task switching examines factors that affect the decision and ability of individuals to switch between tasks with varying levels of interdependence, as well as discuss the mediators and moderators that determine adaptive switching in today's complicated work environments. This model affords a comprehensive understanding of how individuals adapt to dynamic, environmentally-triggered performance demands requiring them to change tasks, teams, and technologies, and shift back and forth between personal, team, and system goals. Our research will be useful for investigating task switching in any modern-day organization facing complex collaborative challenges, such as NASA space exploration, large scientific consortia (e.g., CERN - the European Council for Nuclear Research), cybersecurity teams, healthcare systems, and the military. Furthermore, findings could then be leveraged to develop system-wide interventions that increase overall work efficiency and resilience in safety-critical systems.
Task Progress:	Over the course of this research program, we (1) explore issues that can arise when astronauts switch between tasks, teams, and technologies within the complex, multiteam systems that characterize operations on the International Space Station (ISS) and during Long Duration Space Exploration (LDSE), as well as (2) investigate the effects of astronaut task, team, and technology switches on individual-, team-, and system-level performance. In particular, astronauts work individually as well as within and across different teams to accomplish their work. They also complete a variety of tasks and engage a variety of technologies in the process. Shifting across these tasks, teams, and tools hold the potential for "switch costs" in the form of process loss and performance decrements. Aspects of the various tasks, teams, and technologies make switching to/from each more/less seamless. We explore the implications of effective/efficient switching. In this review period (year 7), we have collected data in SIRIUS '21 to begin to understand the effects of variables across our conceptual framework on individual and team task-switching performance, preferences, and motivations. For this mission, we created new task prompts and increased the number of team tasks to be completed. In conjunction with the NEK SIRIUS-21 mission, we assembled two "twin teams" composed of Northwestern University undergraduate students to take part in the same team and multi-team exercises as the SIRIUS-21 crew outside of isolation. These teams had seven members to correspond to each of the SIRIUS-21 crew roles, plus one backup crewmember. The qualifications for recruitment were designed to mirror those of similar missions. Specifically, we looked for students with science, technology, engineering and mathematics backgrounds and/or military experience and enthusiasm for the project. Potential participants were asked to fill out a recruitment survey that asked questions about their background, and availability, as well as questions designed to gauge interest. These questions included: "Why do you want to participate?", "What makes you a good team member?", and "Would you consider going to Mars?" After identifying those whose backgrounds matched our criteria and meeting with the students to explain the demands of the project, we composed two twin teams. Each team was constructed to have the most diversity among backgrounds, gender, race, and nationality. The twin teams met at least once per week either in person at the ATLAS laboratory at Northwestern University or on Zoom (depending on the Northwestern University academic calendar) to conduct the same team tasks as the SIRIUS-21 crew for the duration of the eight-month mission. Twin teams would meet once a week for an hour to take part in the Team Task Battery. Once a month, each team would meet for two hours to complete Project RED live with the SIRIUS-21 crew. During Project RED, the SIRIUS-21 crew interacted with one twin team or the other (alternating each time) via laptops to complete a complex problem-solving task. The teams also met for 5 additional hours spread throughout the 8 months to complete the Hidden Profile decision-making task. Many of these meetings were early in the morning to accommodate either the schedules of the SIRIUS-21 crew (in the case of Project RED) or the schedules of the Northwestern University students.
