Performance Goal Text:			
Task Description:	Bedrest is an excellent analog for the study of on-orbit musculoskeletal changes that occur during long-duration spaceflight. Our novel approach involve quantifying typical daily loads to the lower extremities in selected free-living volunteer subjects who are moderate exercisers and planning individual exercise prescriptions based on DLS theory. Subjects were randomized to control or exercise groups and confined to 6-degree head-down bedrest in the General Clinical Research Center (GCRC) at the Cleveland Clinic for 12 weeks. During this time, the exercise group underwent individualized daily exercise programs in the unique Zero Gravity Locomotion Simulator (ZLS) at CCF designed to replace their daily mechanical load stimulus experienced during free living. DXA, MRI, and QCT scans were conducted at the start and end of bedrest to assess variations in bone mineral density, changes in muscle volume, and regional changes (cortical vs. trabecular) in bone. Strength measurements were collected pre- and post-bedrest, and urinary and serum markers of bone resorption and formation were also assessed. Dietary intake sufficient to maintain constant body		

	weight with a balanced intake of macro- and micronutrients was planned and supervised by a registered dietician, and a physician was available 24 hr/day to attend to any medical needs. A rehabilitation program was offered to subjects in the 8 weeks following bedrest. The proposed experiment should provide a categorical answer to the question of whether intermittent load replacement can adequately protect the musculoskeletal system against hypokinetic osteopenia and muscle atrophy and may open a new era in individualized exercise countermeasure planning.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	The information obtained as a result of this study will provide further insight into the role of skeletal loading in bone loss during long-duration spaceflight, and knowledge gained from this research will thereby contribute to a better understanding of the importance of exercise for the development and maintenance of bone strength among humans living in Earth gravitational fields. Knowledge in this area is crucial to the treatment of bone disease for which exercise may or may not be an effective intervention.
Task Progress:	The previous two fiscal years have been very productive for this project. During this time GCRC support was obtained and an infrastructure was established to carry out the research. The first four campaigns, (including a total of 4 control and 3 exercise subjects), have been successfully completed. The fifth campaign is currently underway and involves one female subject who is an exercise subject. In collaboration with an NSBRI-funded project, the NASA Glenn Research Center and CCF project team developed a passive pneumatic subject load device (pSLD). This device uses a single pneumatic cylinder to provide a nearly constant spring force on the cables attached to the subject harness. The pSLD was used for one exercise subject in campaign 2 and two exercise subjects in campaign 3 and functioned reliably. The exercisers in campaign 3 wore customized harnesses with bilayer-padded shoulder straps. The exerciser in the previous campaign wore a harness with single-layer-padded shoulder straps. The project team has modified existing mathematical theories on daily load stimulus (DLS) incorporating new theories on saturation and recovery of the osteogenic potential of bone with distributed mechanical loading and the effects of standing. Extensive MATLAB code has been written and is in its final stages of completion, allowing users to analyze complete sets of in-shoe force data and calculate DLS. This revised DLS is being used to formulate the individualized exercise prescriptions used by the exercising subjects. The revised algorithm is currently being implemented into a toolkit for the real-time processing of test subject force-plate data. Details of these findings were recently presented at the American Society of Biomechanics meeting in Stanford.
