Flight Program:			
Flight Assignment:	NOTE: End date changed to 09/30/2025 per A. Beitman/HFBP. Original end date was 09/30/2027 (Ed., 8/14/25).		
Key Personnel Changes/Previous PI:	There was a change in Principal Investigator (PI) from Alexander C. Stahn, PhD to Christopher W. Jones, PhD as the previous PI (Dr. Stahn) accepted a new position at an institution outside of the U.S. Dr. Jones is well qualified to fulfill the role of PI given his background in neuroscience and substantial experience researching the neurobiological and neurobehavioral effects of stress exposure associated with living and working in isolated, confined, and extreme (ICE) and controlled (ICC) environments. [Note: Per the PI, Dr. Stahn continues as a Co-Investigator on the study. (Ed., 11/7/24).]		

COI Name (Institution):	Basner, Mathias M.D., Ph.D. (University of Pennsylvania) Dinges, David Ph.D. (University of Pennsylvania) Kuehn, Simone Ph.D. (Max Planck Institute for Human Development, Berlin, Germany) Roalf, David Ph.D. (University of Pennsylvania) Mühl, Christian (German Aerospace Agency (DLR)) Gerlach, Darius (German Aerospace Agency (DLR)) Gur, Ruben Ph.D. (University of Pennsylvania) Johannes, Bernd (German Aerospace Agency (DLR)) Piechowski, Sarah (German Aerospace Agency (DLR)) Bell, Suzanne Ph.D. (NASA Johnson Space Center) Stahn, Alexander (Charité – Universitätsmedizin Berlin)
Grant/Contract No.:	80NSSC22K0648
Performance Goal No.:	
Performance Goal Text:	
Task Description:	With prolonged mission durations, spaceflight crews will become increasingly dependent on onboard technologies for knowledge acquisition and maintenance. It is expected that not all skills and knowledge required for these missions can be retained and retrieved based on pre-mission training alone. Limited and delayed communication will constrain support from Mission Control and less assistance will be available when performing mission-critical operations, such as post-landing operations. With the present project we will target NASA's particular interest in developing and assessing an adaptive, just-in-time countermeasure that will consolidate and improve skills that are most relevant to space flight operations. To achieve this aim, NASA established a Virtual NASA Specialized Center of Research (VNSCOR) referred to as the "Mars Adaptive Training Integrative Knowledge System (MATRIKS)", which is comprised of the following projects: (1) "Trinity – Multi-Environment Virtual Training for Long Duration Exploration Missions", (PI: A. Anderson, CU Boulder); (2) "Morpheus – A Haptic Sensory Supplement to Optimize In-Flight Adaptive Training for Human Control of Spacecraft Robotic Arms" (PI: S. Robinson, UC Davis); and the present project "Neo – Adaptive Training integrative knowledge System to Improve Operational Performance and its Neural Basis for Spaceflight" (PI: C.W. Jones, UPenn). Neo leverages a validated workstation, Six Degrees of Freedom (6DF), that simulates a rendezvous and docking maneuver using real spacecraft flight dynamics. It is designed to (1) train and improve sensorimotor skills relevant for inflight and post-landing operational tasks; (2) feature an autonomous and adaptive training approach that does not rely on feedback from flight operations on the ground; (3) maximize the transfer of mission-relevant motor skills; (4) allow the assessment of the neural circuitry underlying the task; and (5) deliver the training in a motivating and meaningful way to astronauts. Neo comprises two overarching aims: First, we will identify the neural circuitry underlying spaceflight relevant tasks by performing a subset of 6DF tasks during functional magnetic resonance imaging (fMRI) in up to N=30 healthy adults with varying levels of 6DF experience. Second, we will integrate the proposed 6DF autonomous intelligent tutor system in an additive manner with a haptic feedback intervention (Morpheus) and multi-environment virtual trainer (Trinity) as part of the VNSCOR MATRIKS. It is expected that Neo, Morpheus, and Trinity mutually complement each other to produce an effective countermeasure tool to acquire and retain operational skills that are critical for exploration-class missions. To assess the efficacy of this combined effort, the VNSCOR MATRIKS will collect data in one 45-day HERA campaign of N=16 crewmembers (four missions with N=4 crewmembers each). The primary goal is to identify changes in operational performance, indexed by the Robotic On-board Trainer for Research (ROBoT-r), in response to MATRIKS. As part of Neo, we will also examine whether the effects of MATRIKS transfer to general cognitive functioning (indexed by performance on the Cognition test battery), distinctive visuospatial abilities critical for performing telerobotic tasks (indexed by performance on the Spatial Cognition battery), and brain structure and neural circuitry of key brain networks relevant for spaceflight-related performance.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	The expected significance of this project relates to its relevance for facilitating effective countermeasure tools to acquire and retain operational skills that are critical for exploration class missions. At the conclusion of the research, we will have defined and demonstrated the use of a neuroscience-based, adaptive training integrative knowledge system to potentially mitigate visuospatial and sensorimotor brain changes associated with prolonged isolation and confinement to reduce the likelihood or impact of potential decrements in human performance capabilities during long-duration space missions. Together, these data will help mission planners to ensure safe and successful space exploration class missions. It is possible that the results from this project also translate to situations on Earth where fine motor skills are essential, such as robot-assisted surgery.
Task Progress:	NOTE: Continuation of "Mars Adaptive Training Integrative Knowledge System (MATRIKS) to Improve Operational Performance and Its Neural Basis for Spaceflight" with new Principal Investigator (PI) Dr. Christopher Jones. Previous PI was Dr. Alexander Stahn, who relocated to Europe. See prior reporting under Stahn for additional information. The primary objectives for Year 3 were to optimize the imaging protocol, including the task-related functional MRI (fMRI) protocol simulating a spaceflight maneuver leveraging the proposed 6DF training system, and to complete the integration, processing, and analysis of data collected in the pilot in-lab study at the Deutsches Zentrum Fuer Luft- Und Raumfahrt (DLR). [Ed. Note: DLR is the German Space Agency.] The work in Year 3 was characterized by the application and approval of a project supplement to account for the delay in the NASA Human Exploration Research Analog (HERA) Campaign 8 (C8) and a change in the project's PI due to a change in institution of the original PI (Dr. Stahn). During the third funding year, work on the project has continued according to the updated project timeline, which reflects changes made to the project during both the Definition Phase and supplement. Data collection in the N=30 healthy adults who participated in the DLR Study was successful, yielding 100% of expected data collected. Data were assessed for completeness and underwent quality control prior to processing. The following data types and quantities were collected: 1. MRI: Measuring neural anatomy and task-dependent functional activation, a total of N=30 structural and N=30 functional MRI scans were collected. 2. 6DF: Measuring operationally-relevant performance, a total of N=30 6DF sessions were collected consisting of N=960 individual 6DF trials. 3. Cognition: Measuring cognitive performance, a

	total of N=60 Cognition test batteries were collected consisting of N=600 Cognition tests. 4. Spatial Cognition: Measuring spatial cognition performance using eight separate tests indexing navigation search and strategy, as well as spatial orienting and updating, a total of N=240 spatial cognition tests were collected. 5. Surveys: Four different surveys, totaling N=120 surveys, were collected that measured participant demographics, handedness (Edinburgh Handedness Inventory), computer experience, and sense of direction. The following project milestones were achieved in the third year of the study: 1. Supplemental proposal: To extend the project duration to address the delay of HERA C8, a project supplement was revised according to NASA's feedback, submitted, and approved. 2. PI Change: Due to the previous project PI leaving the University of Pennsylvania for a position outside of the U.S., a change in the project's PI to Christopher W. Jones effective August 2024, was submitted and approved by NASA. 3. Optimizing MRI protocol in HERA: Work continued optimizing the MRI protocol for HERA by integrating information learned from the dry runs and DLR Study. 4. Data analysis: Analysis of the MRI data collected in the in-lab study at DLR has progressed. MRI data acquired from a total of N=30 subjects (N=12 experts and N=18 novices) have been analyzed to evaluate the regional activation profiles between experienced and novice individuals to elucidate the neural circuitry underlying operationally-relevant task performance.
