Flight Assignment:	NOTE: start date changed to actual start date of NNJ04HD83G (jvp 1/2010)		
Key Personnel Changes/Previous PI:			
COI Name (Institution):	Bedford, Joel (Colorado State University) Liber, Howard (Colorado State University)		
Grant/Contract No.:	NNJ04HD83G		
Performance Goal No.:			
Performance Goal Text:			

Task Description:	For extended missions in space, astronauts will be exposed to a radiation environment unlike any on the earth's surface. Galactic cosmic rays include a particularly worrisome component of energetic iron nuclei which are high atomic number, high energy (HZE) charged particles with linear energy transfer (LET) similar to alpha particles but with very different track structures. While the relative biological effectiveness (RBE) of a particular radiation roughly depends on the LET, the very different track structures for these two radiations may well modulate this RBE even if they have identical average LETs. Further, this "radiation quality" for the exposures actually relevant for astronauts will be modified by interactions with materials in the spacecraft, including their own bodies. Basic to virtually all relevant biological effects of ionizing radiation is the underlying damage produced in DNA, and the subsequent cellular processing of such damage. The damage can be qualitatively different for different kinds of radiations, and the genetics of the biological systems exposed can greatly affect damage processing and ultimate outcome—the biological effect of concern. The accurate repair of DNA double-strand breaks (DSB) is critical for the maintenance of genomic integrity and function. Incorrect repair of such lesions results in chromosome rearrangements and mutations that can lead to cancer and heritable defects in the progeny of irradiated parents. It is important, therefore, to understand cellular responses to DNA damage and to elucidate the mechanisms and phenotypic consequences of DSB misrepair. Our general aim in this proposal is to examine connections between cellular radiosensitivity phenotypes relevant for carcinogenesis, namely chromosome aberration formation, mutagenesis and telomere fusions, and deficiencies in various components of the non-homologous end joining system, using RNA interference to systematically knockdown gene products known to be involved, either singly or in combination.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	
Task Progress:	Our continued experiments will lead to valuable information regarding CPR question 10.12, “What are the effects of inter-individual diversity?” We hypothesize that NHEJ repair components are major genetic determinants controlling individual susceptibility to radiation-induced cancer, as well as heritable effects of exposure. Therefore, naturally occurring deficiencies of these proteins within the population will put these individuals at increased risk. Our RNAi approach of experimentally mimicking highly relevant human deficiencies will shed light of this important issue. We also anticipate impact on CPR question 10.07, “What are the cancer risks in humans from spaceflight?” We anticipate that our characterization of telomere dysfunction, chromosome aberration formation and gene mutation will serve as informative surrogate endpoints for predicting cancer risks. Strikingly, our initial and very preliminary experiment at Brookhaven with 1GeV iron, demonstrated elevated levels of inappropriate telomere fusion and mutation in DNA-PKcs deficient cells, as compared to ?-ray exposure.
