Performance Goal Text:			

Task Description:	A novel method using an Electrostatic Levitator (EL) is proposed to determine the surface tension of liquid/gas systems. This key thermophysical property is key to predicting optimum conditions for additive manufacturing, materials processing, and welding operations in space and on ground. The novel method for measurement of surface tension proposed involves the use of electrostatically forced Faraday instability. In this method, an oscillatory electrostatic forcing is applied to a liquid system, resulting in sudden pattern formation at the interface, i.e., an instability is caused. The "instability" is a result of resonance between the imposed forcing frequency and the natural frequency of the system. The critical amplitude and mode shapes are predictable from theory and compared with experiments. The measurement of surface tension directly aligns with the goals of the Thermophysical Property Measurement emphasis of the current NRA (NASA Research Announcement). Faraday experiments by this team using mechanical forcing have shown excellent agreement between theory and experimental results. However, in the case of mechanical forcing, the force of gravity overwhelms the effects of surface tension on the system stability and therefore it is almost impossible to determine this property with accuracy. Electrostatic forcing counters gravity, allowing the effects of surface tension to play a significant role in the ultimate determination of the system stability. Accordingly, experimentally mapped stability curves can be fit accurately with theoretical curves, allowing for the determination of the surface tension with great accuracy. The proposing team has successfully used electrostatic forcing in ground equipment to show that Faraday waves can be obtained as per theoretical predictions. The current state of the art uses an open container geometry to hold the liquid. However, a levitated sphere may also be used, and our proposal uses this containerless method. We therefore propose experiments with an important novel aspect. We propose to use ground-based facilities at JAXA (Japan Aerospace Exploration Agency) and NASA Marshall Space Flight Center (MSFC) to obtain tension for liquids using electrostatic Faraday forcing in using spherical drops by oscillating the drop over a large range of frequencies until the drop resonates with different modal patterns. The surface tension obtained from resonance at one modal patterns will be verified from deduced surface tension from another modal patterns. This will provide a self-consistent bench mark for determining surface tension. In summary, the research allows an alternate new method, viz., Faraday instability, for the determination of surface tension. Using electrostatic forcing instability will permit an independent confirmation of measurements obtained by the single-pulse oscillating-drop technique where decay rates are measured and related to surface tension and viscosity. The proposed method will also provide a slef consistent bench mark. Ground-based research using the electrostatic levitator available at the NASA MSFC and JAXA, and space experiments on ELF in the International Space Station (ISS) will provide accurate data. In addition to being an alternative method for surface tension measurement, the proposed technique also has versatility as a potential means in measuring surface tension for high viscosity materials and two-liquid interfacial tension on ground as well as in space. The proposing team has recently collaborated successfully with JAXA and has conducted experiments to study the feasibility of electrostatic Faraday instability. These results form the basis for the current proposal.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	Accurate surface tension values lead to transformative impact with space and Earth benefits such as a) Additive manufacturing of metals, where knowledge of surface tension is pivotal for predictive modeling to avoid rippling during solidification and possible wrinkling and shrinkage.. Human Exploration: Technology Area (TA) TA7.2.3.5: Welding, TA12.1.2: Computationally-Designed Materials, TA12.4.2.5: Additive Manufacturing. b) Space enabling operations. One example is joining operations such as soldering, where the surface plays an important role in the structure and stability of the weld. Accurate values for the surface tension will enhance the safety and effectiveness of this type of operation in space where the microstructures formed are different than those on Earth where gravity is present. c) Semiconductor crystal growth, where the interfacial tension between a liquid melt and liquid encapsulant plays a large role in determining conditions where convection is present.
Task Progress:	Progress: Significant advancements were achieved in this project during the past funding period. Key accomplishments include: a) From August 2023 to November 2023, 19 metal samples were successfully tested on the ELF. These tests confirmed the project's proposed concept. b) The most crucial finding is that the method of multiple resonant mode forcing can reliably determine the surface tension of liquid metals using a self-confirming technique. c) Several students were supported, and a patent disclosure was filed. d) An additional 19 samples of 99Nb2O3-1Fe2O3, FeO, Pt, and Zr will be tested in a future flight scheduled between February and March 2025. e) In the upcoming period, we will provide open-source software to analyze our data, which will be uploaded to the Physical Sciences Informatics Database.
