Performance Goal No.:			
Performance Goal Text:			

Task Description:	Exposure to ionizing radiation represents one of the most significant health risks to astronauts during both short, but particularly long, duration spaceflight. Vascular endothelial cells (ECs), the most radiosensitive vascular cell type, remain the major regulating interface between the blood and vessel wall. There, they act as a paracrine organ releasing signaling molecules that regulate vessels tone, permeability and cell and platelet adhesion. Dysfunction of the endothelium may result from both an increase in endothelial cell damage (oxidative stress with nitroso-redox imbalance), an impairment of the endothelial repair mechanisms (decrease in the number and function of endothelial progenitor cells) or an acceleration of endothelial cell senescence. Radiation is known to induce cellular oxidative stress, as well as suppress bone marrow proliferation. Data from our lab suggests that gamma and heavy iron ion radiation results in the activation of the ROS producing enzyme xanthine oxidase (XO). Activation of enzymes such as arginase results in a decrease in endothelial protective nitric oxide (NO) with altered nitroso-redox balance and endothelial damage. We hypothesize that radiation will result in activation of ROS producing enzymes that will result in increased oxidative stress, nitroso-redox imbalance and endothelial cell damage. We also hypothesize that radiation will decrease endothelial repair mechanism by reducing bone marrow derived endothelial progenitor cells (EPCs). Additionally, we hypothesize that radiation will accelerate endothelial cell senescence by decreasing telomerase activity and increasing the rate of telomere attrition. This will ultimately result in significant endothelial dysfunction, mimic the aging phenotype and accelerate the development of atherosclerosis. We will test the countermeasure hypothesis that the XO inhibitor (oxypurinol) will reduce radiation related endothelial dysfunction, that arginase inhibition (which reciprocally regulates nitric oxide synthase) will restore nitroso-redox balance and promote endothelial cell protection. We will also test the hypothesis that statins (endothelial cell protectants through a number of pleotropic effects independent of their lipid lowering effects) will prevent oxidative stress, improve nitroso-redox imbalance, enhance endothelial progenitor cell production, and prevent telomere decay. In this way, the adverse effects of radiation on the endothelial cell will be attenuated.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	The current work being performed has the potential to protect humans undergoing either diagnostic radiation procedures or radiation treatment for cancerous tumors.
Task Progress:	The DHE fluorescence rate in the aorta segments of rats exposed to 1 Gy was significantly greater than that of control rats (8.45e-5±0.733e-5 sec-1 versus 4.84e-5±1.29e-5 sec-1, $p<0.05$). Furthermore, 30 minutes of Oxp incubation significantly attenuated the DHE response in irradiated aorta. Following 10-5M ACh administration, aortas of 0Gy rats demonstrated a 25% fluorescent rate increase from baseline slope (125±8.42%), while aortas of the 1Gy-irradiated rats have a negligible response (97.0±6.22%). Dietary XO inhibition elevated this response significantly, compared to untreated, 1Gy irradiated rats (159±19.4%, $P<0.05$). The SNP response between groups is similar, implying that DAF-FM loading is consistent and sufficient. In the study of chronic XO inhibition, rats exposed to 100cGy radiation possessed a significantly elevated Pulse Wave Velocity (PWV) (4.45±0.244 m/sec, n=8) from 0cGy-exposed rats (n=10, $P<0.01$) and 100cGy Oxp-diet rats (n=6, $P<0.05$). The PWV measurements in 0cGy and 100cGy+Oxp rats are not statistically different. The aorta of 5Gy irradiated rats demonstrate a significantly elevated XO activity from controls ($P<0.05$, unpaired Student t test). Remarkably, this activation is abolished by Oxp dietary inhibition ($P<0.01$, unpaired Student t test), endothelium removal ($P<0.05$, paired Student t test), and allopurinol treatement ($P<0.001$, paired Student t test). Total XO+XDH activity was not significantly affected by radiation or Oxp diet. As a result, the aortic XO:XDH activity ratio was increased by 5Gy-radiation, whereas Oxp treatment significantly reduced the ratio ($P<0.001$, unpaired Student t test).
