Grant/Contract No.:	NCC 9-58-CA00405		
Performance Goal No.:			
Performance Goal Text:			

Task Description:	While our previous focus had remained on altered adrenergic signaling (from baroreceptor to adrenergic receptor) in the patho-physiology of orthostatic intolerance, the potential role of nitric oxide, a critical modulator of both cardiac and vascular function became the focus of our investigation. In the vasculature, we have identified novel mechanisms by which NO regulates vascular endothelial function. We have also demonstrated that enhanced NO dependent signaling (as a result of NOS phosphorylation) contributes to vascular contractile hyporesponsiveness, a central component of orthostasis. We are currently using in-vivo techniques to non-invasively and serially measure vascular stiffness (as measured by pulse wave velocity) and determine the contribution of altered arterial compliance to OI. In addition, one of our graduate students, Mr. Eric Tuday, was selected as a summer intern at the Johnson Space Center, in Drs. Janice Meck's and Steven Platt's Cardiovascular Laboratories. His collaborative studies with our and Dr. Platt's group has proven to be very fruitfull and we will be determining the changes in aortic and arterial compliances before, during and after long term bed rest in human volunteers. These studies test the hypothesis that long term bed rest increases arterial compliance which subsequently can decrease the cardiac output response during orthostatic challenges. With regard to the heart, we have determined for the first time that it is not loss of cardiac mass, but altered contractile function that contribute to OI. This depressed contractile function is likely the result of altered adrenergic signaling (of which we have identified a novel arm of the beta-l beta-2 AR signaling pathway) or altered NO signaling. We have made significant contributions to the understanding of the intricate molecular mechanisms underlying the role of NO in the modulating cardiac contractile structure and function in general. We continue to determine the role of dysregulated NO in the pathobiology of orthostatic intolerance. We now have a greater appreciation for the NO signaling dysregulation in 0I and are uniquely poised to test the efficacy of the countermeasures aimed at regulating NO as laid out in our original proposal. We currently have a patent on the target site to inhibit ArginaseII. We are currently working with a venture capital group to further fund work to develop a specific designer drug which will inhibit ArginaseII.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	These findings could have important therapeutic significance for both astronauts, long-term bed rest patients, and the aging populations. All of these groups are predisposed to orthostatic intolerance upon returning to normal gravity and returning to the upright position respectively.
Task Progress:	1. The role of the endothelium and the NO/cGMP pathway in vascular hypo-responsiveness and remodeling in microgravity is nearly completed and will be finalized with manuscripts mid year of year 3 of this proposal. 2. The role of NO in modulating myocardial contractility and hypertrophy has just begun and we have finished the first of a series of studies during year 3, this coming year, of the project. 3. Whether up-regulation of the NO/cGMP system results in decreased vascular and ventricular stiffness as measured by integrated cardiovascular function and ventricular-vascular coupling will begin toward the end of year 3 of this project. We have delayed working on this aspect of the project since it relies on using our chronic rat preparation. This preparation requires that we purchase micro vascular pressure telemetry system to monitor the rats on a 24 hour basis. 4. We have been able to show the disregulation in vascular smooth muscle and currently has a target site by which this disregulation occurs. Our data demonstrating that endothelial cells isolated from ArgII -/- mice are resistant to ROS production and a decrease in NO in response to OxLDL suggests that it is the endothelium that is the target for arginase inhibition. 5. In our animal models we have used aortic atherosclerosis and plaque formation as the target endpoint as this is an accessible site for the study of the vascular changes. Since it is well accepted that dysfunctional endothelium is the root cause of initiating the atherosclerotic process Arg II would promise to be a target for all sites of atherosclerosis.
