Performance Goal No.:			
Performance Goal Text:			
Task Description:	Therapeutic efficacy and safety of pharmaceuticals flown on the space shuttle and International Space Station (ISS) remain critical issues for successful NASA medical operations. Preliminary studies indicated significant differences in potency of some pharmaceutical preparations flown on space flights compared to ground-based controls. This project addresses Question number 11 of Clinical Capabilities in the Critical Path Roadmap. We hypothesize that space flight environment, especially radiation, affects stability of pharmaceuticals contained in the space shuttle and ISS medical kits. The objectives are to 1) determine chemical and physical stability parameters of select pharmaceuticals contained in the shuttle and ISS medical kits along with matching ground-based controls; 2) characterize degradation profiles of the unstable formulations after exposure to particulate radiation using synchrotron light and radiation sources; and 3) develop mathematical models that can predict shelf life of pharmaceuticals during space flight. Select dosage forms from the medical kits returned to Earth after a space flight will be analyzed and compared to		

Task Description:	matching formulations stored under controlled conditions on Earth. Disintegration, dissolution rates and concentrations of active drug and degradation products of these dosage forms will be determined. Effects of high-energy radioactive particles on the stability of these pharmaceuticals will be examined by exposing the formulations to synchrotron light and radiation sources at Brookhaven National Laboratories. Predictive degradation models will be constructed from these data to estimate the degree and magnitude of loss of pharmaceutical activity during space flights. In addition to providing information on pharmaceutical stability in space, the proposed research will also identify if there is a need to develop special pharmaceutical preparations that can ensure stability and resultant therapeutic efficacy of pharmaceuticals in space.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	This research expands and adds to current understanding of medication and dosage form stability. The primary customer inside NASA is the astronaut flight crew and flight medicine by improving and optimizing medical kit configuration. Understanding medication stability in spaceflight benefits the crew by ensuring treatment success. The primary application of this research outside NASA, primarily by optimization of medicine storage or optimization of medical kit configuration in special environments such as military, maritime, and remote and isolated research outposts.
Task Progress:	Some medications which were flown in spaceflight were shown to have reduced stability by either a reduction in active drug content or alteration of physiochemical properties, such as color changes or altered drug dissolution rates. A rigorous experimental protocol investigating drug stability on long duration missions in spaceflight has been planned and awaits launch. A rigorously designed follow up study using ionizing radiation has been proposed and accepted; its initiation is planned for the Summer of 2006.
