Grant/Contract No.:	NNX13AL10A		
Performance Goal No.:			
Performance Goal Text:			

Task Description:	NOTE: Continuation of NNX10AE01G, Material Ignition and Suppression in Space Exploration Atmospheres, with the same principal investigator, Prof. Carlos Fernandez-Pello. Central Objectives: The next generation of NASA spacecraft will use lower pressures and increased oxygen concentrations than current designs. Although there is insufficient knowledge about fire behavior of materials in these Space Exploration Atmospheres (SEA), recent research suggests that material ignitability is increased in SEA. These results imply that next generation spacecraft present a greater fire safety hazard than current designs. The flammability, or fire hazard, of materials is normally assessed by the material's ease of ignition, rate of flame spread, heat released and extinction. In this research project, an experimental investigation is conducted to study the flammability of thermoplastic materials under SEA is being conducted. Methods/techniques: The proposed experimental apparatus is simple and easily incorporated in the Combustion Integrated Rack on the International Space Station (ISS). It consists of a small-scale cylindrical flow duct that has fuel samples attached to its inside wall. A cylindrical radiant heater is located at the center of the duct. An oxidizer gas flows at down the length of the tube. Electrical igniters are placed downstream of each fuel sample. Time to ignition and the time between introduction of suppression agent and extinction are measured as a function of environmental conditions. The normal gravity and microgravity experimental programs will be supported by a comprehensive model of piloted ignition and extinction of materials in SEA. Microgravity experiments will be used to validate the model, which in turn will be used to predict the fire behavior of different combustible materials in SEA. Perceived Significance: Currently, there exists no testing methodology specifically designed to determine the fire hazards of materials under those conditions. The proposed work will fill that void and provide additional information about the effect of SEA on the flammability and suppression of materials. It will also provide guidance to interpret and extend current NASA testing procedures to SEA.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	The project is intended to enhance the ability to predict ignition, burning (flame spread and mass burning), and extinction characteristics of materials in their end use configuration. This approach is called performance based design in terrestrial fire protection engineering. Computational support for this approach requires detailed information about material thermal and combustion properties. Our work on MIST will use experimental data to validate computer models attempting to predict fire behavior using material property estimation techniques. These techniques are currently a focus of research in fire protection engineering.
Task Progress:	The present Summary of Research report describes the work undertaken during this reporting period on the MIST project. Most of the normal gravity work has concentrated in conducting experiments to study the effect of Normoxic environments on the downward spread of flames and the mass burning of polymethylmethacrylate (PMMA) rods of several diameters. These experiments were conducted in the pressure vessel previously described. The results of this work show that moving to environments with reduced ambient pressure and increased oxygen concentration increases the flammability of the PMMA cylinders, resulting in faster flame spread rates. It was also found that the flame spread rate in normoxic environments increases linearly with high oxygen concentration, while the surface regression rate decreases as the normoxic conditions are changed to lower pressure and elevated oxygen concentration. Both results indicate that cautions should be taken when applying simplified analyses of flame spread and surface regression to future spacecraft environments. In addition, significant modifications have been implemented in the test apparatus of the MIST normal gravity experiment to incorporate the radiant heaters as they will be used in the MIST flight experiments.
