Flight Assignment:			
Key Personnel Changes/Previous PI:			
COI Name (Institution):	Rudnick, Joseph (University of California) Hahn, Inseob (Jet Propulsion Laboratory) Ulf, Israelsson (Jet Propulsion Laboratory) Zappoli, Bernard (Toulouse Space Centre)		
Grant/Contract No.:	None		
Performance Goal No.:	1.24		
Performance Goal Text:	To explore the frontiers of physics and unlock mysteries of the universe obscured by Earth's gravity		

Task Description:	Scaling theories describing the behavior of thermophysical properties near critical points were developed using the homogeneity postulate. These models led to the definition of universality classes where critical points of the same class are predicted to have the same critical exponents. Efforts to test these models near a liquid-gas critical point in ground-based laboratories are limited due to the gravity-induced vertical density gradient associated with the divergence of the isothermal compressibility. This density gradient becomes appreciable as the critical point is approached, leading to a significant smearing of the transition. Calculations have shown that in a microgravity environment accurate, gravity free, heat capacity and isothermal susceptibility measurements could be obtained two orders of magnitude in reduced temperature closer to the critical point. Ground-based high-precision measurements performed in the gravity-affected as well as the gravity-free regions can also be used to test recent predictions of crossover equation-of-state models. High-resolution sensors are required for the temperature, pressure, and density measurements. The objectives of this task are to test the scaling equation-of-state predictions at the liquid-gas critical point of 3He. The task objectives will include: 1) Measurements of the heat capacity at constant volume along the critical isochore above and below the transition, and measurements of the isothermal susceptibility along the critical isochore above the transition and along the coexistence curve below the transition to determine the critical amplitudes and exponents associated with these diverging thermodynamic quantities. 2) Measurements of the density dependence of the pressure along the critical isotherm to determine the asymptotic critical amplitude and exponent for this diverging quantity. 3) Measurements along the coexistence curve to determine the asymptotic critical amplitudes and exponents associated with the isothermal susceptibility and the shape of the coexistence curve. 4) A rigorous test of equation-of-state predictions both in the asymptotic and crossover regions. The ability to perform these simultaneous measurements should permit a more accurate determination of the asymptotic critical exponents and amplitudes and test asymptotic equation-of-state predictions. Furthermore, knowledge of the asymptotic amplitudes (and exponents) will permit more stringent tests of crossover theories that apply farther away from the critical point. Critical phenomena exist not only in liquid-gas systems, but also in many other real-world systems such as magnetic systems, binary alloys, superconductors and superfluids. In fact the same scaling theory, being tested by MISTE, could apply to many seemingly different physical systems. Thus a high-precision examination of the scaling theory from MISTE constitutes a fundamental test of our basic understanding of material behavior.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	
Task Progress:	This last year has seen the publication of several articles of experimental and theoretical studies related to the MISTE experiment. A theoretical analysis of 3He critical point measurements titled “Comparison of Theoretical Models of Crossover Behavior near the 3He Liquid-Vapor Critical Point” was published in Physical Review E. The three advanced crossover models tested where the minimal subtraction renormalization model (Dohm and co-workers), massive renormalization model (Bagnuls and Bervillier), and the crossover parametric model (Anisimov and co-workers). In addition, we have re-analysed the high precision microgravity heat capacity measurements in SF6 using the minimal subtraction renormalization model. This paper titled “Reanalysis of Microgravity Heat Capacity Measurements Near the SF6 Liquid-Gas Critical Point,” was published in the Int. J. of Thermophys. This re-analysis revealed an unexpectedly large asymptotic region that appears not to be consistent with renormalization predictions. A major issue regarding the proposed design of the MISTE flight cell was an uncertainty in the expected thermal time constant as the critical point was approached. A theoretical analysis of the 2-D piston effect has now given sufficiently accurate predictions of the relaxation time. This work described in a manuscript titled “Temperature and Density Relaxation Close to the Liquid-Gas Critical Point: an Analytical Solution for Cylindrical Cells” has been accepted for publication in Physical Review E. A recent analysis of earlier thermodynamic measurements near the 3He liquid-gas critical (Anisimov, M.A., F. Zhong, and M. Barmatz, “Resolving the Yang-Yang Dilemma in 3He Near the Critical Point,” J. Low Temp. Phys. 137, 69 (2004)) revealed subtle gravity effects (previously ignored) that require the careful placement of the pressure sensor within the experimental cell. The existing pressure sensor has been repositioned within the experimental cell to minimize gravity effects. We have redesigned and fabricated a new type of miniaturized high-resolution thermometer, using the metalized paramagnetic compound of PdMn. This new type of HRT has a fast equilibration and less susceptible to moisture contamination than an original GdCl3 salt type. We have also redesigned and fabricated a new capacitive density sensor using copper coated sapphire disks. The new density sensor has much improved parallelism between two electrodes. It also conducts much faster any electrical field induced heat within the capacitor gap. The updated MISTE low temperature probe is now going through calibration tests in preparation for thermodynamic measurements throughout the critical region. A new probe is also being fabricated to provide better thermal isolation in future planned experiments. An advanced data analysis approach that includes the calculation of confidence contours has also been developed to compare our thermodynamic measurements to theory. That approach was recently used in the reanalysis of SF6 microgravity specific heat measurements.
