Performance Goal No.:			
Performance Goal Text:			

Task Description:	To determine if a slow, laser-cooled atom microgravity experiment can improve the sensitivity to an electron electric dipole moment (e-EDM) by orders of magnitude. Develop and test experimental features such as electric field quantization, multiple quantum transitions, beam focusing and reflection, electric field ramping, pulsed oscillatory fields, state selection and Stark separated levels. Detemine sensitivity to systematic effects, sensitivity to electric and magnetic noise. Perform other tests and measurements incidental to these. Will determine the most useful features to incorporate, identify problem areas, and help assess the feasibility of proceeding to flight definition studies for a microgravity electron electric dipole moment experiment.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	Spinoff can improve accuracy of cesium atomic clocks in space and on Earth.
Task Progress:	A proof-of-principle electron electric dipole moment (e-EDM) experiment using slow cesium atoms, nulled magnetic fields, and electric field quantization has been completed, the data analyzed, and a manuscript published in Physical Review A78 063416 (2007). With the ambient magnetic fields seen by the atoms reduced to less than 200 pT, an electric field of 6 MV/m lifts the degeneracy between states of unequal mF and, along with the low (3 m/s) velocity, suppresses the systematic effect from the motional magnetic field.
