Performance Goal No.:			
Performance Goal Text:			

Task Description:	ACES (Atomic Clock Ensemble in Space) is a European Space Agency (ESA) project that will test fundamental physics, search for the time variation of fundamental constants, and enable highly precise frequency comparisons between clocks on Earth. It is planned to operate for at least 18 months on the International Space Station. PHARAO (Projet d'Horloge Atomique par Refroidissement d'Atomes en Orbit) is the laser-cooled, microgravity, atomic cesium clock of ACES that provides state-of-the-art accuracy, with a goal of 1 part in 10^(16) accuracy. We will assist in the accuracy evaluation of PHARAO, a central scientific objective of the ESA mission. We will contribute to the analysis of the three largest sources of systematic uncertainty: clock frequency shifts due to the collisions of ultracold atoms, a Doppler shift known as the distributed cavity phase shift, and a frequency shift due to the lensing of the atomic wavepackets by the clock's microwave field. The initial working uncertainty budget projected an accuracy of 2.2×10^(-16). The proposed work will reduce the largest contribution to the clock's uncertainty to negligible levels and investigate significant reductions of others, with a goal of reaching 10^(-16) accuracy. The work will help define the limits of PHARAO's accuracy and identify workable procedures to demonstrate its accuracy. The PI will also participate in a study on space optical clocks as a member of NASA's science definition team (SDT) for optical clocks and time transfer.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	Our work on microwave cavities produced an improved design that will be used for Cs and Rb fountain clocks. These are being incorporated into new clocks being built at the British, Canadian, South Korean, Polish, and Indian National Laboratories. The new cavity design allows significantly reduced clock errors due to Doppler shifts. Our work has also led to a deeper understanding of the microwave lensing frequency shift that is being used as a correction of International Atomic Time, including the correction for the PHARAO clock. More broadly, our work contributes to scientific progress towards anticipated future optical frequency atomic clocks.
Task Progress:	We have completed the pre-launch accuracy evaluation of the microgravity PHARAO clock. A paper describing this accuracy evaluation and space qualification of PHARAO has been submitted. The paper significantly improves PHARAO’s expected accuracy on-orbit and shows that it can reach its accuracy goal after 18 months of operations, and below 1 part in 10^16 for comparisons with cesium ground clocks. The evaluation procedure developed in the paper is a new approach, accurately evaluating the correction for PHARAO operating at a nominal density and launch velocity. This nominal operating point provides PHARAO a high frequency stability for dedicated approximately 10-day long comparisons with ground clocks. The high accuracy and stability of PHARAO is needed for the mission objective of ACES, to test general relativity, to probe the time variation of fundamental constants, and to compare high-performance ground clocks worldwide. We are also actively participating in NASA's science definition team (SDT) study for optical clock and time transfer.
