Performance Goal Text:			

Task Description:	Cool flames have significant implications for the control of engine knocking, ground and space fire safety, and combustion emissions. The recent International Space Station (ISS) combustion science experiments on flame extinguishment discovered the existence of cool flames for both large single droplets and droplet arrays after radiative extinction. Numerical simulations of droplet combustion also provide an explanation for the transition of hot flame to cool flame after radiative extinction. However, it remains unclear at what conditions the hot flames transfer to cool flames and how the cool flame flammable region is related to hot flame flammability limit and extinction limit. It is also not clear how oxygen concentration, dilution, pressure, diffusion, and convection transport processes affect the cool flame transition. More importantly, due to limits of space and payload, the ISS experiments did not provide detailed speciation and temperature distributions of cool flame structures for quantitative validation of kinetics and radiation model. By using the Flame Extinguishment (FLEX) experimental data from the Physical Sciences Informatics (PSI) system of combustion science, we propose to conduct new simulations and ground-based experiments using ozone-sensitized counterflow flames to * develop a new diagram of the flammability limits of diffusional cool flames affected by radiation, diffusion, and convection ; * bridge the knowledge gap between the flammability limits and extinction limits of hot flames and cool flames ; * predict and answer the question at what conditions the transition from hot flame extinction to cool flames is possible and verify the phenomena observed on the ISS flame extinguishment experiments ; * obtain new, quantitative data of extinction limit, flame temperature, and species distribution for the validation of kinetic and radiation models involving cool flames ; * extend the cool flame experiments from the original ISS droplet experiments to a more general ground-based combustion system involving radiation, diffusion, convection, and low-temperature chemistry while maintaining a one-dimensional geometry. The proposed new ground-based experiments and data analysis are complimentary to and not directly linked with the science objectives from the original ISS combustion science investigation, and will significantly advance the understanding of near-limit cool flame dynamics and contribute to the future control of engine knocking, ground and space fire safety, and combustion emissions.
Rationale for HRP Directed Research:	
Research Impact/Earth Benefits:	An experimentally validated dimethyl ether (DME) and methane cool flame kinetic model was developed. The results showed that the existing kinetic model significantly over-predicts the cool flame extinction limits. However, by targeting the exothermic reactions of cool flames using the cool flame extinction limits, an updated chemical kinetic model for dimethyl ether/methane mixtures is developed and validated. This study shows the value of the ozone-assisted counterflow cool flame platform in examining the key reactions contributing to the heat release rate in cool flames. Diffusion warm flames of n-alkanes were successfully established. The warm flame of n-alkanes is dramatically influenced by the reactant concentrations and mixture temperatures. The primary cool flame stage is favored at lower temperatures, but the secondary warm flame stage is favored at elevated temperatures. Moreover, near extinction, the multistage warm flame collapses to a primary oxidation zone, governed by peroxy chemistry, whereas the secondary oxidation stage, governed by intermediate chemistry, is dominant near autoignition conditions. The results show that warm flames serve as a critical bridge between cool flames and hot flames. The counterflow cool flame extinction provides a good validation target and explanation for the NASA droplet cool flame extinction limit. In addition, the results benefit the development of efficient and low mission advanced engines for transportation.
Task Progress:	For detailed summaries of the progress of this project, the Principal Investigator refers NASA Task Book visitors to the published papers listed in the cumulative bibliography. These papers describe the motivation for the work as well as detailing the experimental hardware and data analysis procedures, computational methods, and results. They constitute the final report for this project. (Ed., 11/16/22)
